Conduction Characteristics of MOS Transistors (for fixed Vds)

- MOS transistors are majority-carrier devices.
- For n-channel transistors, the majority carriers are electrons conducted through a channel.
- A positive gate voltage (w.r.t. substrate) enhances the number of carriers in the channel, and increases conduction.
- Threshold voltage V_{tn} denotes the gate-to-source voltage above which conduction occurs.
- For enhancement mode devices, V_{tn} is positive; for depletion mode devices, V_{tn} is negative.
- p-channel devices are similar to n-channel devices, except that all voltages and currents are
- in opposite polarity.

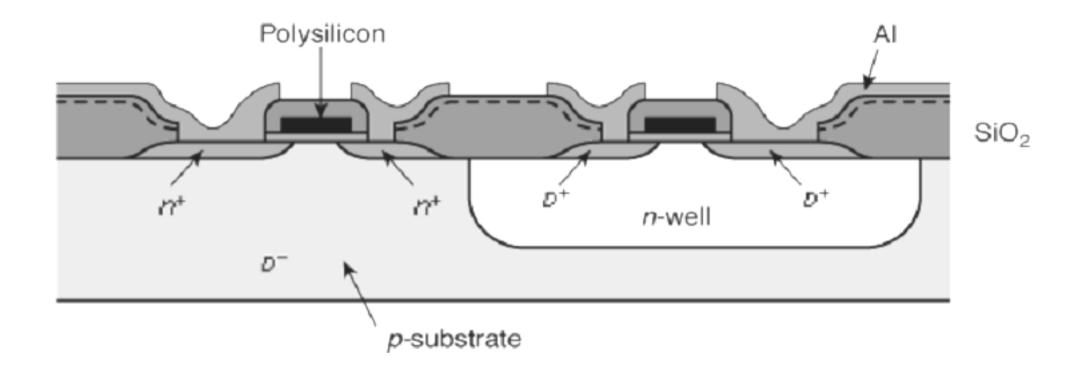

MOS Transistor

- Shown here is the cross-section of an n-channel enhancement transistor:
- Substrate is moderately doped with p-type material. Substrate in digital circuit is usually connected to V_{Gnd} (ground).
- The source and drain regions are heavily doped with n-type material through diffusion. These are often referred to as the **diffusion** regions.

MOS transistors - Types and Symbols

Threshold Voltage: Concept

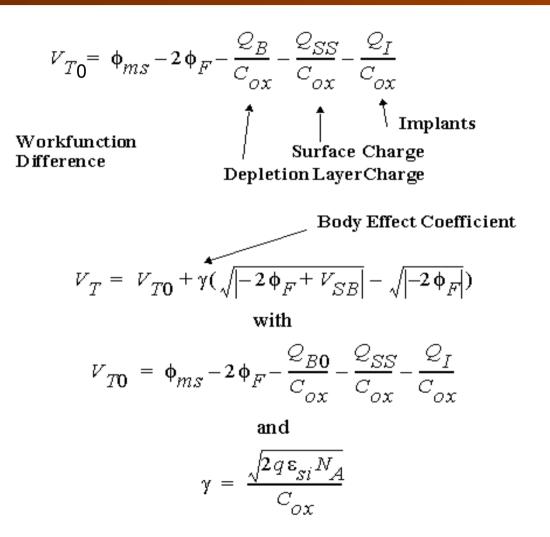

MOS transistor (1)

- Between the diffusion regions is the gate area form from a layer of polycrystaline silicon (known as polysilicon). This is separated from the substrate by a layer of thin oxide (made of silicon dioxide). Polysilicon is reasonable conductor and form the gate electrode.
- Underneath the thin oxide and between the n+ regions is the channel. The channel is conducting when a suitable electric field is applied to the gate.
- Due to geometric symmetry, there are no distinctions between the source and drain regions. However, we usually refer the terminal with more positive voltage the drain (for n-type) and less positive voltage the source.
- For a zero gate bias and a positive V_{DS}, no current flows between the drain and source because of the two reverse biased diodes shown in the diagram. The drain and source are therefore isolated from each other.
- Assuming that the substrate is always at the most negative supply voltage, these two diode should never become forward bias under normal operation.

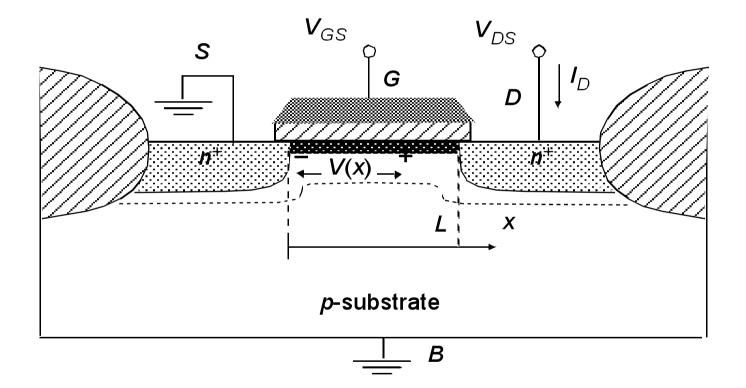

MOS transistor (2)

- When a positive voltage is applied to the gate, an electric field is produced across the substrate which attracts electrons toward the gate. Eventually, the area under the gate changes from p-type to n-type, providing a conduction path between the source and drain.
- The gate-source voltage V_{GS} when a channel starts to form under that gate is called the threshold voltage V_T.
- The surface underneath the gate under this condition is said to be inverted. The surface is known as the inversion layer.
- As larger bias is applied to the gate the inversion layer becomes thicker
- An other p-n junction exists between the inversion layer and the substrate. This diode junction is field induced. Contrast this with the p-n junction between the source (or drain) and the substrate, which is created by a metallurgical process.

Current-Voltage Relations

Linear Region: $V_{DS} \leq V_{GS} - V_T$

$$I_D = k_n \frac{W}{L} \left((V_{GS} - V_T) V_{DS} - \frac{V_{DS}^2}{2} \right)$$

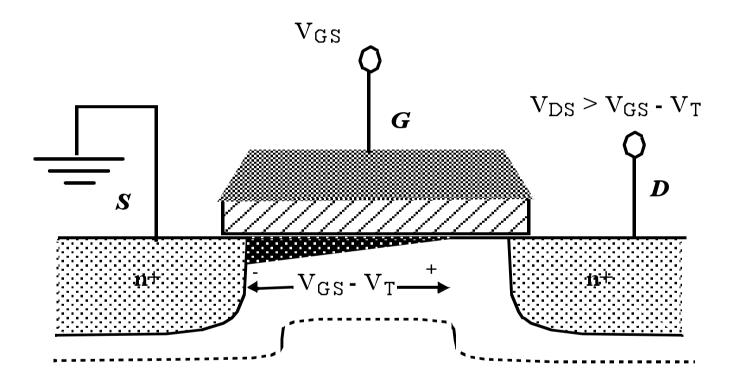

with

$$k'_n = \mu_n C_{ox} = \frac{\mu_n \varepsilon_{ox}}{t_{ox}}$$

Process Transconductance Parameter

Saturation Mode: $V_{DS} \ge V_{GS} - V_T$ Channel Length Modulation $I_D = \frac{k'_n W}{2 L} (V_{GS} - V_T)^2 (1 + \lambda V_{DS})$

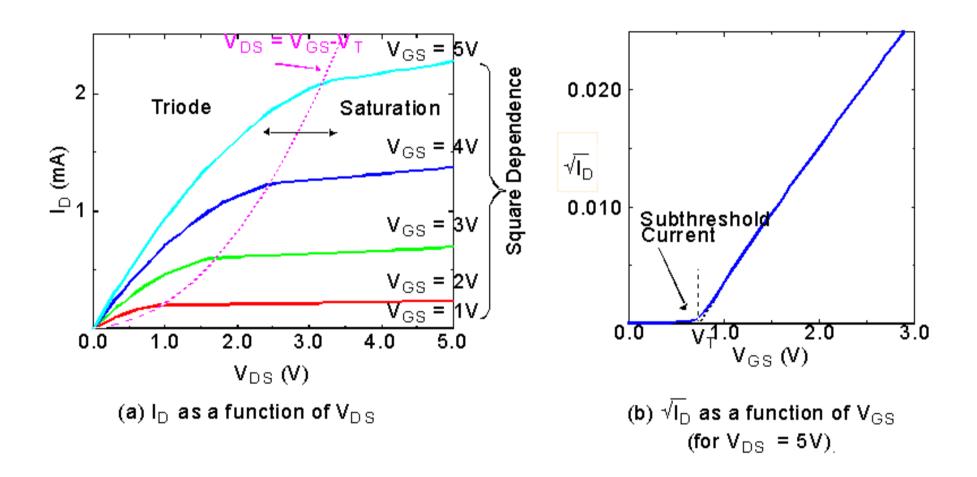

Transistor in Saturation

MOS transistor (3)

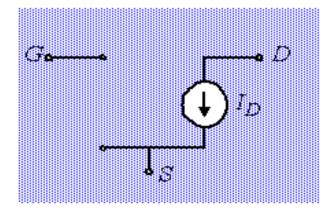

- As a voltage is applied between the source and drain, the inversion layer becomes thinner at the drain terminal due to interaction between V_G and V_D.
- If V_{DS} < V_{GS} V_T, then the drain current Id is a function of both V_{GS} and V_{DS}. Furthermore, for a given V_{DS}, I_D increases linearly with (V_{GS} V_T). The transistor is said to be operating in its linear or resistive region.
- If V_{DS} > V_{GS} V_T, then V_{GS} < V_T and **NO** inversion layer can exist at the drain terminal. The channel is said to be '*pinched-off*'. The transistor is operating in the saturation region, where the drain current is dependent on V_{GS} and is almost independent of V_{DS}.

A model for manual analysis

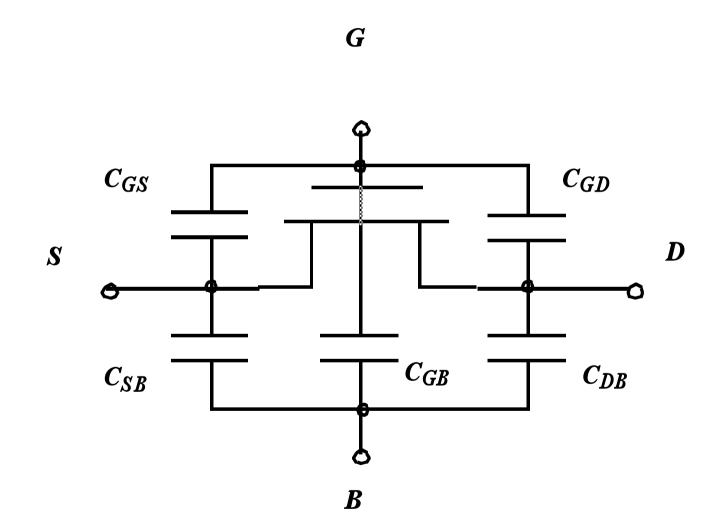

$$\begin{split} V_{DS} &> V_{GS} - V_T \\ I_D &= \frac{k'_n W}{2} (V_{GS} - V_T)^2 (1 + \lambda V_{DS}) \\ V_{DS} &< V_{GS} - V_T \\ I_D &= k'_n \frac{W}{L} \Big((V_{GS} - V_T) V_{DS} - \frac{V_{DS}^2}{2} \Big) \end{split}$$

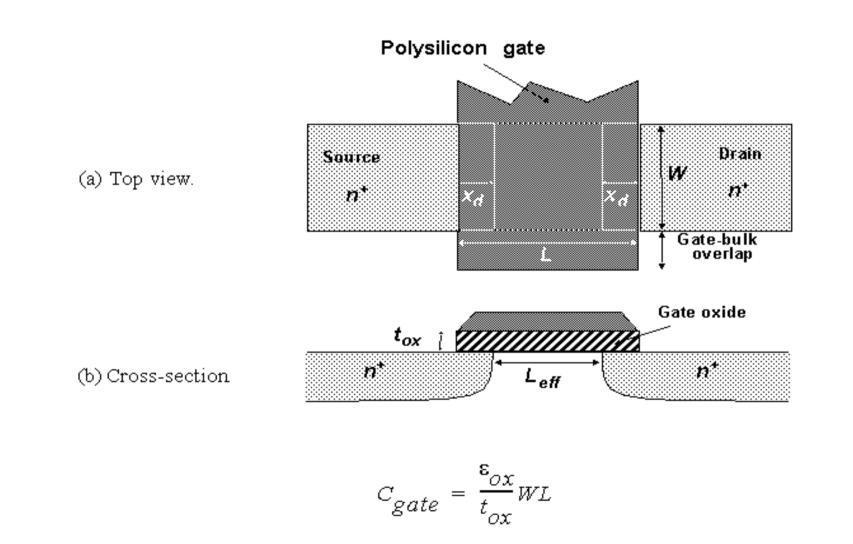

with

$$V_T = V_{T0} + \gamma (\sqrt{\left|-2\phi_F + V_{SB}\right|} - \sqrt{\left|-2\phi_F\right|})$$

What is SPICE Circuit Simulator?

- **SPICE** is a widely-used circuit-level simulator, originally from Berkeley.
- We use an industrial version **HSPICE** in the Department
 - You can download WinSPICE which is free (see course web page)
- SPICE uses numerical techniques to solve nodal analysis of circuit. It supports the following:
 - Textual input to specify circuit & simulation commands
 - Text or graphical output format for simulation results
- You can use SPICE to specify these circuit components:
 - Resistors, Capacitors, Inductors
 - Independent sources (V, I), Dependent sources (V, I)
 - Transmission lines
 - Active devices (diodes, BJTs, JFETS, MOSFETS)
- You can use SPICE to perform the following types circuit analysis:
 - non-linear d.c.
 - non-linear transient
 - linear a.c.
 - Noise & temperature

SPICE MODELS

Level 1: Long Channel Equations - Very Simple

Level 2: Physical Model - Includes Velocity Saturation and Threshold Variations

Level 3: Semi-Emperical - Based on curve fitting to measured devices

Level 4 (BSIM): Emperical - Simple and Popular
